

STATS 217: Introduction to Stochastic Processes I

Lecture 23

Continuous time Markov chains

- This week, we will study continuous time Markov chains.
- As before, we will assume that the state space is discrete. *(often, it will be finite)*
- We will also assume that the Markov chains under consideration are time-homogeneous i.e. that the transition rates do not depend on the time.

Continuous time Markov chains

Recall: stochastic process $(X_t)_{t \in \mathcal{T}}$

We say that $(X_t)_{t \geq 0, t \in \mathbb{R}}$ is a **(time-homogeneous) continuous time Markov chain (CTMC)** on the state space Ω if

$$\mathbb{P}[X_{t+s} = j \mid X_s = i, X_{s_{n-1}} = i_{n-1}, \dots, X_{s_0} = i_0] = \mathbb{P}[X_{t+s} = j \mid X_s = i]$$

↙ markov property

(Note: In the original image, wavy lines are drawn under X_{t+s} and X_s , and horizontal lines are drawn under $X_{s_{n-1}} = i_{n-1}, \dots, X_{s_0} = i_0$.)

Continuous time Markov chains

We say that $(X_t)_{t \geq 0, t \in \mathbb{R}}$ is a **(time-homogeneous) continuous time Markov chain (CTMC)** on the state space Ω if

$$\begin{aligned} \mathbb{P}[X_{t+s} = j \mid X_s = i, X_{s_{n-1}} = i_{n-1}, \dots, X_{s_0} = i_0] &= \mathbb{P}[X_{t+s} = j \mid X_s = i] \\ &= \mathbb{P}[X_t = j \mid X_0 = i] \\ &=: p_{ij}^t. \quad (p^t)_{ij} \end{aligned}$$

time homogeneity \rightarrow

Continuous time Markov chains

We say that $(X_t)_{t \geq 0, t \in \mathbb{R}}$ is a **(time-homogeneous) continuous time Markov chain (CTMC)** on the state space Ω if

$$\begin{aligned}\mathbb{P}[X_{t+s} = j \mid X_s = i, X_{s_{n-1}} = i_{n-1}, \dots, X_{s_0} = i_0] &= \mathbb{P}[X_{t+s} = j \mid X_s = i] \\ &= \mathbb{P}[X_t = j \mid X_0 = i] \\ &=: p_{ij}^t.\end{aligned}$$

- for all integers $n \geq 0$,
- for all $0 \leq s_0 < s_1 < \dots < s_{n-1} < s$,
- for all $0 \leq t$, and
- for all $j, i, i_0, \dots, i_{n-1} \in \Omega$.

Continuous time Markov chains

We say that $(X_t)_{t \geq 0, t \in \mathbb{R}}$ is a **(time-homogeneous) continuous time Markov chain (CTMC)** on the state space Ω if

$$\begin{aligned}\mathbb{P}[X_{t+s} = j \mid X_s = i, X_{s_{n-1}} = i_{n-1}, \dots, X_{s_0} = i_0] &= \mathbb{P}[X_{t+s} = j \mid X_s = i] \\ &= \mathbb{P}[X_t = j \mid X_0 = i] \\ &=: p_{ij}^t.\end{aligned}$$

- for all integers $n \geq 0$,
- for all $0 \leq s_0 < s_1 < \dots < s_{n-1} < s$,
- for all $0 \leq t$, and
- for all $j, i, i_0, \dots, i_{n-1} \in \Omega$.

As before, we will let P^t denote the $|\Omega| \times |\Omega|$ matrix with $P^t(i, j) = p_{ij}^t$.

Example

- Let $N(t)$ denote a PPP with rate λ .
- Then, $N(t)$ is a CTMC on the state space $\mathbb{Z}^{\geq 0}$ with transition probabilities

$$\mathbb{P}[X_t = j \mid X_0 = i] = \mathbb{P}[\text{Pois}(\lambda t) = (j - i)].$$

$$= \frac{e^{-\lambda t} (\lambda t)^{j-i}}{(j-i)!}$$

Example

- Let $N(t)$ denote a PPP with rate λ .
- Then, $N(t)$ is a CTMC on the state space \mathbb{Z} with transition probabilities

$$\mathbb{P}[X_t = j \mid X_0 = i] = \mathbb{P}[\text{Pois}(\lambda t) = (j - i)].$$

→ "continuisation of a DTMC"

- For a very general example, suppose that Y_n is a DTMC with state space Ω and with transition probabilities U_{ij}
- Then, $X_t = Y_{N(t)}$ is a CTMC on the state space Ω

$\gamma_0, \gamma_1, \gamma_2, \gamma_3, \gamma_4, \dots$

Example

- Let $N(t)$ denote a PPP with rate λ .
- Then, $N(t)$ is a CTMC on the state space \mathbb{Z} with transition probabilities

$$\mathbb{P}[X_t = j \mid X_0 = i] = \mathbb{P}[\text{Pois}(\lambda t) = (j - i)].$$

- For a very general example, suppose that Y_n is a DTMC with state space Ω and with transition probabilities U_{ij}
- Then, $X_t = Y_{N(t)}$ is a CTMC on the state space Ω with transition probabilities

$$\mathbb{P}[X_t = j \mid X_0 = i] = \sum_{\ell \geq 0} \mathbb{P}[X_t = j \mid X_0 = i, N(t) - N(0) = \ell] \cdot \mathbb{P}[N(t) - N(0) = \ell]$$

e.g. exactly two transitions have happened
(\Leftrightarrow) exactly two $\mathbb{P}\Omega$ in $[0, t]$
 $(U^2)_{ij}$

Example

- Let $N(t)$ denote a PPP with rate λ .
- Then, $N(t)$ is a CTMC on the state space \mathbb{Z} with transition probabilities

$$\mathbb{P}[X_t = j \mid X_0 = i] = \mathbb{P}[\text{Pois}(\lambda t) = (j - i)].$$

- For a very general example, suppose that Y_n is a DTMC with state space Ω and with transition probabilities U_{ij}
- Then, $X_t = Y_{N(t)}$ is a CTMC on the state space Ω with transition probabilities

$$\begin{aligned}\mathbb{P}[X_t = j \mid X_0 = i] &= \sum_{\ell \geq 0} \mathbb{P}[X_t = j \mid X_0 = i, N(t) - N(0) = \ell] \cdot \mathbb{P}[N(t) - N(0) = \ell] \\ &= \sum_{\ell \geq 0} (U^\ell)_{ij} \left\{ e^{-\lambda t} \frac{(\lambda t)^\ell}{\ell!} \right\}\end{aligned}$$

Heat kernel

- Given the transition matrix U on Ω , the **heat kernel** H_t is defined on $\Omega \times \Omega$ by

$$H_t(i, j) = \sum_{\ell \geq 0} (U^\ell)_{ij} \cdot e^{-\lambda t} \frac{(\lambda t)^\ell}{\ell!}.$$

$\mathbb{P} [X_t = j \mid X_0 = i]$

$X_t = Y_{N(t)}$

Y has transition matrix U .

Heat kernel

- Given the transition matrix U on Ω , the **heat kernel** H_t is defined on $\Omega \times \Omega$ by

$$H_t(i, j) = \sum_{\ell \geq 0} (U^\ell)_{ij} \cdot e^{-\lambda t} \frac{(\lambda t)^\ell}{\ell!}.$$

- The previous slide shows that H_t is the time t transition matrix of the CTMC $X_t = Y_{N(t)}$, where Y is a DTMC with transition matrix U and $N(t)$ is a PPP with rate λ .

Heat kernel

- Given the transition matrix U on Ω , the **heat kernel** H_t is defined on $\Omega \times \Omega$ by

$$H_t(i, j) = \sum_{\ell \geq 0} (U^\ell)_{ij} \cdot e^{-\lambda t} \frac{(\lambda t)^\ell}{\ell!}$$

- The previous slide shows that H_t is the time t transition matrix of the CTMC $X_t = Y_{N(t)}$, where Y is a DTMC with transition matrix U and $N(t)$ is a PPP with rate λ .
- A more compact way to write H_t is as

$$e^x = 1 + x + \frac{x^2}{2!} + \frac{x^3}{3!} + \dots$$

$$H_t = e^{\lambda t(U-I)} = \underline{\underline{e^{tQ}}},$$

where Q denotes the $\Omega \times \Omega$ matrix $Q = \lambda(U - I)$.

$$e^{t\lambda(Q-I)} = \underbrace{e^{-t\lambda I}}_{\text{identity matrix}} \cdot \underline{e^{t\lambda U}}$$

\downarrow
 $1 \times 1 \times 1 \times 1$
 identity matrix

Jump rates

- For a DTMC, the transition matrix encodes the probability of transitioning from one state to another in the first step.

is there something like this for CTMC?

for DTMC:

$$P_{ij} = \mathbb{P}[X_1 = j | X_0 = i]$$

Jump rates

- For a DTMC, the transition matrix encodes the probability of transitioning from one state to another in the first step.
- In continuous time, the 'first step is infinitesimally small'.

Jump rates

- For a DTMC, the transition matrix encodes the probability of transitioning from one state to another in the first step.
- In continuous time, the 'first step is infinitesimally small'.
- Accordingly, we define the **jump rates** by

Recall :

$$p_{ij}^h = \mathbb{P}[X_h = j | X_0 = i] \quad q_{ij} := \lim_{h \rightarrow 0} \frac{p_{ij}^h}{h} \quad \forall i \neq j.$$

Jump rates

- For a DTMC, the transition matrix encodes the probability of transitioning from one state to another in the first step.
- In continuous time, the 'first step is infinitesimally small'.
- Accordingly, we define the **jump rates** by

$$q_{ij} := \lim_{h \rightarrow 0} \frac{p_{ij}^h}{h} \quad \forall i \neq j.$$

- We will set

$$q_{ii} = - \sum_{j \neq i} q_{ij} =: -\lambda_i \quad \begin{array}{l} \text{because of this} \\ \sum_j q_{ij} = 0 \end{array}$$

Jump rates

- For a DTMC, the transition matrix encodes the probability of transitioning from one state to another in the first step.
- In continuous time, the 'first step is infinitesimally small'.
- Accordingly, we define the **jump rates** by

$$q_{ij} = \lim_{h \rightarrow 0} \frac{p_{ij}^h}{h} \quad \forall i \neq j.$$

- We will set

$$q_{ii} = - \sum_{j \neq i} q_{ij} =: -\lambda_i.$$

$$\lambda_i = \sum_{j \neq i} q_{ij}$$

- In particular, for any $i \in \Omega$,

$$r_{ij} := \frac{q_{ij}}{\lambda_i} \quad j \neq i$$

is a probability distribution on $\overline{\Omega \setminus \{i\}}$.

Example

$$q_{ij} = \lim_{h \rightarrow 0} \frac{(p^h)_{ij}}{h}$$

- For a PPP with rate λ , the only non-zero jump rates are $q_{i,i+1} = \lambda$ for all $i \geq 0$ and $q_{ii} = -\lambda$ for all $i \geq 0$.

$$\begin{aligned}(p^h)_{ij} &= \mathbb{P}[X_n = j \mid X_0 = i] \\ &= \mathbb{P}[Poi(h) = (j-i)]\end{aligned}$$

$$j = i+1 \quad = \quad \underbrace{e^{-\lambda h}}_1 \frac{(\lambda h)^1}{1!} h$$

Example

- For a PPP with rate λ , the only non-zero jump rates are $q_{i,i+1} = \lambda$ for all $i \geq 0$ and $q_{ii} = -\lambda$ for all $i \geq 0$.
- For $X_t = Y_{N(t)}$ as before, where Y_n is a DTMC on the state space Ω with transition probabilities U_{ij} , the jump rates are (for $i \neq j$)

$$(p^h)_{ij} = (e^{hQ})_{ij}$$
$$Q = \lambda(U - I)$$

$$q_{ij} = \lim_{h \rightarrow 0} \frac{p_{ij}^h}{h}$$
$$= \lim_{h \rightarrow 0} \frac{(e^{hQ})_{ij}}{h}$$

Example

- For a PPP with rate λ , the only non-zero jump rates are $q_{i,i+1} = \lambda$ for all $i \geq 0$ and $q_{ii} = -\lambda$ for all $i \geq 0$.
- For $X_t = Y_{N(t)}$ as before, where Y_n is a DTMC on the state space Ω with transition probabilities U_{ij} , the jump rates are (for $i \neq j$)

$$\begin{aligned}q_{ij} &= \lim_{h \rightarrow 0} \frac{p_{ij}^h}{h} \\&= \lim_{h \rightarrow 0} \frac{(e^{hQ})_{ij}}{h} \\&= Q_{i,j} \\&= \lambda(U_{ij} - I_{ij}) \\&= \lambda \cdot U_{ij} \quad \text{since } i \neq j.\end{aligned}$$

Example

- For a PPP with rate λ , the only non-zero jump rates are $q_{i,i+1} = \lambda$ for all $i \geq 0$ and $q_{ii} = -\lambda$ for all $i \geq 0$.
- For $X_t = Y_{N(t)}$ as before, where Y_n is a DTMC on the state space Ω with transition probabilities U_{ij} , the jump rates are (for $i \neq j$)

$$\begin{aligned}q_{ij} &= \lim_{h \rightarrow 0} \frac{p_{ij}^h}{h} \\&= \lim_{h \rightarrow 0} \frac{(e^{hQ})_{ij}}{h} \\&= Q_{i,j} \\&= \lambda \cdot (U - I)_{i,j} \\&= \lambda \cdot U_{ij}.\end{aligned}$$

Example

- Typically, it is easier to describe a CTMC using jump rates and then compute the transition probabilities from the jump rates.

◦ intermediate q : if you have the jump rates, how do you simulate the process

Example

- Typically, it is easier to describe a CTMC using jump rates and then compute the transition probabilities from the jump rates.
- As an example, consider a continuous-time branching process where each individual independently dies at rate μ and gives birth to a new individual at rate λ .
- This corresponds to a CTMC with the jump rates

$$\left. \begin{aligned} q(n, n+1) &= \lambda n \\ q(n, n-1) &= \mu n. \end{aligned} \right\} \text{convenient + intuitive.} \\ \text{representation}$$

Example

- Typically, it is easier to describe a CTMC using jump rates and then compute the transition probabilities from the jump rates.
- As an example, consider a continuous-time branching process where each individual independently dies at rate μ and gives birth to a new individual at rate λ .
- This corresponds to a CTMC with the jump rates

$$q(n, n + 1) = \lambda n$$

$$q(n, n - 1) = \mu n.$$

- We will now discuss how to construct a CTMC from the jump rates.

Constructing a CTMC from jump rates

How can we construct/simulate (say on a computer) a CTMC with given jump rates q_{ij} ?

Constructing a CTMC from jump rates

How can we construct/simulate (say on a computer) a CTMC with given jump rates q_{ij} ?

- Recall that for a DTMC (Y_n) on the state space Ω with transition probabilities U_{ij} and for $N(t)$ a PPP with rate λ , the jump rates of $X_t = Y_{N(t)}$ are

$$\rightarrow q_{ij} = U_{ij}\lambda, \quad i \neq j.$$

$$q_{ii} = -\sum_{j \neq i} q_{ij}$$

Constructing a CTMC from jump rates

How can we construct/simulate (say on a computer) a CTMC with given jump rates q_{ij} ?

- Recall that for a DTMC (Y_n) on the state space Ω with transition probabilities U_{ij} and for $N(t)$ a PPP with rate λ , the jump rates of $X_t = Y_{N(t)}$ are

$$q_{ij} = U_{ij}\lambda, \quad i \neq j.$$

- We will basically reverse this process.

→ we have q_{ij}
we will try to
find U_{ij} & λ
s.t. U_{ij} is a valid
transition matrix &
 $q_{ij} = U_{ij}\lambda$

Constructing a CTMC from jump rates

- First, suppose that $\Lambda := \sup_i \lambda_i < \infty$, where recall that $\lambda_i = \sum_{j \neq i} q_{ij}$.

e.g.
$$\left. \begin{aligned} q(n, n+1) &= \lambda n \\ q(n, n-1) &= \mu n \end{aligned} \right\}$$

does not satisfy $\Lambda < \infty$

Constructing a CTMC from jump rates

- First, suppose that $\Lambda := \sup_i \lambda_i < \infty$, where recall that $\lambda_i = \sum_{j \neq i} q_{ij}$.
- Let $N(t)$ be a PPP with rate Λ .

Constructing a CTMC from jump rates

- First, suppose that $\Lambda := \sup_i \lambda_i < \infty$, where recall that $\lambda_i = \sum_{j \neq i} q_{ij}$.
- Let $N(t)$ be a PPP with rate Λ .
- Let (Y_n) be a DTMC on the state space Ω with transition probabilities U_{ij} where

$$q_{ij} = U_{ij} \cdot \Lambda$$

$$U_{ij} = \frac{q_{ij}}{\Lambda} \quad j \neq i$$

$$\sum_{i \neq j} U_{ij} = \frac{\sum_{i \neq j} q_{ij}}{\Lambda} = \frac{\lambda_i}{\Lambda} \leq 1$$

Constructing a CTMC from jump rates

- First, suppose that $\Lambda := \sup_i \lambda_i < \infty$, where recall that $\lambda_i = \sum_{j \neq i} q_{ij}$.
- Let $N(t)$ be a PPP with rate Λ .
- Let (Y_n) be a DTMC on the state space Ω with transition probabilities U_{ij} where

$$\sum_{j \neq i} U_{ij} = \frac{\lambda_i}{\Lambda} \quad \rightarrow \quad \begin{aligned} U_{ij} &= q_{ij}/\Lambda \quad i \neq j \\ U_{ii} &= 1 - \lambda_i/\Lambda. \end{aligned}$$

Constructing a CTMC from jump rates

- First, suppose that $\Lambda := \sup_i \lambda_i < \infty$, where recall that $\lambda_i = \sum_{j \neq i} q_{ij}$.
- Let $N(t)$ be a PPP with rate Λ .
- Let (Y_n) be a DTMC on the state space Ω with transition probabilities U_{ij} where

$$U_{ij} = q_{ij}/\Lambda \quad i \neq j$$

$$U_{ii} = 1 - \lambda_i/\Lambda.$$

- Then, $X_t = Y_{N(t)}$ is a CTMC with jump rate from i to j for $i \neq j$ given by

$$\Lambda U_{ij} = q_{ij},$$

as desired.

Constructing a CTMC from jump rates

- What if $\Lambda = \infty$? For instance, this is the case for the branching process example we discussed earlier.

Constructing a CTMC from jump rates

- What if $\Lambda = \infty$? For instance, this is the case for the branching process example we discussed earlier.
- Given jump rates q_{ij} , let

$$\lambda_i = \sum_{j \neq i} q_{ij}$$
$$U_{ij} := r_{ij} = \frac{q_{ij}}{\lambda_i} \quad i \neq j.$$

Constructing a CTMC from jump rates

- What if $\Lambda = \infty$? For instance, this is the case for the branching process example we discussed earlier.
- Given jump rates q_{ij} , let

$$U_{ij} := r_{ij} = \frac{q_{ij}}{\lambda_i} \quad i \neq j.$$

- Recall that r_{ij} and hence U_{ij} is a probability distribution on $\Omega \setminus \{i\}$.

Constructing a CTMC from jump rates

- Let Y_0, Y_1, \dots denote a DTMC with

$$\mathbb{P}[Y_{n+1} = j \mid Y_n = i] = U_{ij} \quad i \neq j$$
$$\mathbb{P}[Y_{n+1} = i \mid Y_n = i] = 0.$$

Constructing a CTMC from jump rates

- Let Y_0, Y_1, \dots denote a DTMC with

$$\mathbb{P}[Y_{n+1} = j \mid Y_n = i] = U_{ij} \quad i \neq j$$

$$\mathbb{P}[Y_{n+1} = i \mid Y_n = i] = 0.$$

- Given $Y_0 = i_0, Y_1 = i_1, Y_2 = i_2, \dots$, generate independent random variables t_1, t_2, \dots with

$$t_i \sim \text{Exp}(\lambda_{i-1}).$$

Constructing a CTMC from jump rates

- Let Y_0, Y_1, \dots denote a DTMC with

$$\mathbb{P}[Y_{n+1} = j \mid Y_n = i] = U_{ij} \quad i \neq j$$

$$\mathbb{P}[Y_{n+1} = i \mid Y_n = i] = 0.$$

- Given $Y_0 = i_0, Y_1 = i_1, Y_2 = i_2, \dots$, generate independent random variables t_1, t_2, \dots with

$$t_i \sim \text{Exp}(\lambda_{i-1}).$$

- Let $T_0 := 0$ and

$$T_n := t_1 + \dots + t_n.$$

Constructing a CTMC from jump rates

- Let Y_0, Y_1, \dots denote a DTMC with

$$\mathbb{P}[Y_{n+1} = j \mid Y_n = i] = U_{ij} \quad i \neq j$$

$$\mathbb{P}[Y_{n+1} = i \mid Y_n = i] = 0.$$

- Given $Y_0 = i_0, Y_1 = i_1, Y_2 = i_2, \dots$, generate independent random variables t_1, t_2, \dots with

$$t_i \sim \text{Exp}(\lambda_{i-1}).$$

- Let $T_0 := 0$ and

$$T_n := t_1 + \dots + t_n.$$

- Finally, let

$$X(t) = Y_n \quad \forall T_n \leq t < T_{n+1}.$$

Constructing a CTMC from jump rates

- Why does this work?

Constructing a CTMC from jump rates

- Why does this work? \rightarrow wts

$$q_{ij}^{i \neq j} = \lim_{h \rightarrow 0} \frac{p_{ij}^h}{h}$$

- For any $i \neq j$, we have

$$\lim_{h \rightarrow 0} \frac{p_{ij}^h}{h} = \lim_{h \rightarrow 0} \frac{1}{h} \underbrace{\mathbb{P}[\text{Exp}(\lambda_i) \leq h]} \cdot \underbrace{\mathbb{P}[Y_1 = j \mid Y_0 = i]}$$

Constructing a CTMC from jump rates
